

Arabic Voice Robot — Model Stack + VPS Provider Research

Prepared: July 2026

Hardware baseline used in tests: NVIDIA Tesla T4 (~14.9 GB VRAM)

Purpose: Lock the best production model stack, then choose a VPS / GPU cloud provider with capacity, bandwidth, and cost estimates.

1. Executive recommendation

Best model stack (production default)

Family	Winner	Role	Key evidence
ASR	Whisper-Large-v3-Turbo-CT2	Default realtime listener	Robot score 89.62 , Acc 68.4% , RTF 0.046 (~22× realtime), VRAM ~ 2.5 GB
LLM	Nile-Chat-4B	Default conversational brain	Robot score 95.41 , TTFT 0.96 s , 11.56 tok/s , VRAM ~ 8.4 GB
TTS	VoiceTut-TTS	Default speaker	Robot score 90.02 , RTF 0.157 (~6.4×), 82.7 chars/s , VRAM ~ 3.15 GB

Why this trio: Best overall accuracy/speed/VRAM blend for a live Arabic (Egyptian) voice robot on one mid-tier GPU. Combined naive peak VRAM $\approx 2.5 + 8.4 + 3.15 \approx 14.0$ GB, which fits a T4 tightly and fits comfortably on **24 GB** (RTX 4090 / A40-class) with concurrency headroom.

Quality / alternate picks (when UX priority flips)

Need	Pick	Tradeoff
Higher ASR word accuracy	Whisper-Large-v3-CT2	Acc 72.92% , but VRAM ~ 4.3 GB , slower RTF 0.133
Higher LLM answer quality	Qwen3-8B (int4)	Quality 4.65/5 , auto-pass 85% vs Nile 2.81/5 / 20% — but slower TTFT 1.94 s
Balanced LLM mid-GPU	Qwen3-4B-Instruct-2507	Quality 4.41/5 , TTFT 0.95 s , VRAM ~ 8.8 GB
TTS voice naturalness wins	VoiceTut-TTS (listen first)	Keep VoiceTut after human listening QA for Egyptian dialect / code-switch quality

TTS caveat (from bake-off): robot scores cover speed/resources only. Confirm Egyptian dialect / code-switch naturalness by listening to WAVs before freezing VoiceTut.

Best VPS / GPU cloud to interact with

Primary pick: RunPod (Secure Cloud) — RTX 4090 24 GB

Criterion	Why RunPod wins for this project
Interaction	Full SSH/root pods, Docker templates, REST API, serverless endpoints
Fit for stack	24 GB VRAM = ASR+LLM+TTS co-resident with headroom
Billing	Per-second (good for iteration + scale-to-zero patterns)
Ops	Template deploy in ~30s; Community for cheap R&D, Secure for production
Cost vs peers	RTX 4090 ~ \$0.34/hr Community / ~ \$0.69/hr Secure (July 2026 listings)

Secondary: Vast.ai (cheapest RTX 4090, weaker SLA) · **Hetzner** (predictable EU dedicated / monthly) · **DigitalOcean** (simplest DX, higher \$/hr).

RunPod Community vs Secure — detailed difference

RunPod sells the **same GPU SKUs** (e.g. RTX 4090) in two clouds. The GPU chip can be identical; **the hosting environment, reliability, and price are not.**

Dimension	Community Cloud	Secure Cloud
What it is	Peer-to-peer style marketplace of third-party / partner hosts invited and vetted by RunPod	Hardware in Tier 3 / Tier 4 datacenters run with RunPod’s trusted partners (enterprise-style facilities)
Price (RTX 4090, July 2026)	~ \$0.34/hr (cheaper)	~ \$0.69/hr (~2× Community)
Reliability	Good hosts exist, but no strong formal uptime SLA ; machines can go offline / be less redundant on power & network	Built for production: redundancy, faster incident response; marketed with high uptime (RunPod cites 99.9%+ / up to 99.99% class SLAs on Secure / platform docs)
Security / compliance	Multi-tenant container isolation; weaker story for regulated data	Better isolation story; SOC 2 Type II / partner certs (SOC 2, ISO 27001, etc. depending on site) — preferred for client voice audio and production PII
Availability	Supply/price can vary by region and time of day	More predictable capacity for always-on APIs
Best for	Dev, staging, bake-offs, non-critical batch jobs	Live Arabic voice robot serving real users
Risk if it fails mid-call	User hears timeout / dropped session; hard to explain to a client	Much lower chance of random host disappearance

Practical rule for this project

1. Build and test on **Community** (save money while iterating).

2. Move the public API to **Secure** before client demos / soft launch.
3. Same Docker image and model weights transfer between the two — you are mostly paying for **reliability + compliance**, not a different GPU model.

2. Bake-off evidence summary

2.1 ASR leaderboard (top)

Rank	Model	Robot	Acc%	WER	RTF	VRAM MB
1	Whisper-Large-v3-Turbo-CT2	89.62	68.40	0.316	0.046	2492
2	Whisper-Large-v3-CT2	87.92	72.92	0.271	0.133	4316
3	Whisper-Small-CT2	86.19	63.19	0.368	0.084	1340
4	Arabic-Whisper-Turbo-FT-CT2	83.38	60.76	0.392	0.046	1692

Arabic fine-tunes were competitive on speed but did **not** beat base Whisper Large on accuracy in this clip bake-off. Voxtral-Mini is accurate but VRAM-heavy (~11 GB) — poor co-resident with LLM+TTS.

2.2 LLM leaderboard

Rank	Model	Robot	TTFT s	tok/s	VRAM MB	Quality /5	Auto-pass
1	Nile-Chat-4B	95.41	0.96	11.56	8394	2.81	20%
2	Qwen3-4B-Instruct-2507	91.61	0.95	10.48	8758	4.41	80%
3	Qwen3-8B (int4)	30.66	1.94	5.16	6900	4.65	85%
4	ALLaM-7B	4.15	2.47	5.62	15280	4.25	85%

Decision rule from client PDFs: prefer Nile when turn-taking feel matters; switch to Qwen3-8B when answer correctness / TTS-fit matter more. ALLaM-7B exceeds a T4 alone — avoid on ≤16 GB cards.

2.3 TTS leaderboard

Rank	Model	Robot	RTF	chars/s	VRAM MB	Realtime?
1	VoiceTut-TTS	90.02	0.157	82.7	3150	yes
2	SILMA-TTS	77.42	0.238	46.8	3340	yes
3	Chatterbox-Multilingual-V3	28.63	1.101	13.4	4790	no
4	NAMAA-Egyptian-TTS	0.61	1.232	15.1	6066	no

2.4 Combined VRAM budget

Stack	ASR	LLM	TTS	Naive peak sum	Fits
Speed (default)	Turbo ~2.5 GB	Nile ~8.4 GB	VoiceTut ~3.2 GB	~14.0 GB	T4 tight / 24 GB OK
Quality	Large-v3 ~4.3 GB	Qwen3-8B ~6.9 GB	VoiceTut ~3.2 GB	~14.4 GB	T4 tight / 24 GB OK
Avoid	+ ALLaM 15 GB	—	—	overflows mid GPUs	need ≥24–48 GB

Production rule: deploy on **≥24 GB** even if T4 “fits,” so KV-cache, CUDA context, and 2–3 queued turns do not OOM.

3. Workload model (users, usage, bandwidth)

This section sizes **how many people** the robot can serve, **how much they talk**, and **how much network/GPU** that consumes — using **production-style** assumptions (not lab bake-off clip lengths).

Glossary (key metrics)

Term	Meaning
DAU	Daily Active Users — unique people who complete at least one real voice session that calendar day
MAU	Monthly Active Users — unique people active in a 30-day window. For sticky consumer apps, DAU is often ~ 15–25% of MAU (industry stickiness band); AI products often land near ~ 20% DAU/MAU
Session	One continuous conversation (user opens the robot, talks, then leaves)
Turn	One user utterance + one robot reply
Peak concurrent sessions	How many users are in a live call at the same second during the busiest minute — this drives GPU count, not DAU alone
GPU-busy concurrency	How many turns are actively using the GPU at once (usually lower than “connected” sessions if you use VAD / push-to-talk)

Production assumptions (realistic)

Voice products in the wild are **not** 5–6 second lab clips. Conversational / assistant sessions often run **many minutes**; individual user speaking stretches commonly land in the **30 seconds – 2 minutes** range when users explain a problem, dictate, or give multi-step instructions. Voice-heavy platforms also report longer average sessions than text chat (often tens of minutes when users stay in a voice room; for a **task robot**, expect shorter sessions but still multi-turn).

Parameter	Production assumption	Why this number
Avg user utterance (speech in)	~60 s (range 30 s – 2 min)	Mid-point of real explanatory speech; short commands exist, but capacity must plan for long turns
Avg robot reply (speech out)	~35 s	Assistants usually speak less than long user monologues, but Arabic answers + explanations are not 5 s
Sessions / active user / day	Pilot 1 → Scale 2–3	Most users open the robot 1–2 times/day early; power users more
Turns / session	5–8	Multi-step tasks (ask → clarify → confirm → follow-up)

3.1 Audio & GPU usage by stage

What each stage means

Stage	Meaning in product terms	Who is using it
Pilot	Closed alpha / friends & family / internal QA	Team + invited testers; traffic is low and spiky
Soft launch	Limited public beta (one city, one partner, waitlist)	Early adopters; still manually supported
Growth	Open product with marketing; usage climbing week over week	Real customers; need SLA and monitoring
Scale	Established product; multiple campaigns / B2B seats	Must autoscaling; one GPU is no longer enough
Mature (extra)	Large consumer or multi-tenant B2B footprint	Multi-region / multi-GPU fleet

Workload table (production speech lengths)

Formulas used:

- Audio-in hours/day $\approx \text{DAU} \times \text{turns/user/day} \times 60 \text{ s} / 3600$
- Audio-out hours/day $\approx \text{DAU} \times \text{turns/user/day} \times 35 \text{ s} / 3600$
- GPU-seconds/day $\approx \text{turns/day} \times \sim \mathbf{18\text{--}25 \text{ s}}$ wall time per turn on one sequential ASR→LLM→TTS pipeline (Whisper Turbo RTF ~ 0.05 on $\sim 60 \text{ s} \approx 3 \text{ s}$; LLM $\sim 3\text{--}8 \text{ s}$; VoiceTut RTF ~ 0.16 on $\sim 35 \text{ s} \approx 6 \text{ s}$; plus queue/IO)

Stage	DAU	Approx. MAU*	Turns/user/day	Audio-in h/day	Audio-out h/day	Turns/day	Est. GPU-seconds / day
Pilot	100	~500	6	10	5.8	600	~12,000–15,000

Stage	DAU	Approx. MAU*	Turns/user/day	Audio-in h/day	Audio-out h/day	Turns/day	Est. GPU-seconds / day
Soft launch	1,000	~5,000	8	133	78	8,000	~160,000–200,000
Growth	5,000	~25,000	10	833	486	50,000	~1.0M–1.3M
Scale	25,000	~100,000	12	5,000	2,920	300,000	~6M–7.5M
Mature	100,000	~400,000	12	20,000	11,700	1,200,000	fleet / multi-region

*MAU ≈ DAU / 0.20 using a ~20% DAU/MAU stickiness assumption (typical AI / consumer band).

These audio-hour numbers are in the same order of magnitude as high-traffic self-hosted speech systems once you leave “demo clip” lengths — **hundreds to thousands of audio hours/day** at Growth/Scale — which is why GPU count and queueing matter more than raw disk bandwidth.

3.2 Concurrent capacity (one GPU) — explained

With ASR + LLM + TTS on **one RTX 4090**, the GPU usually handles **one full turn at a time** (or a tiny queue). Longer turns (~60 s in + ~35 s out) take roughly **20 s** of GPU work each, so one card sustains about **3–5 turns per minute**.

Users who are silent (VAD / push-to-talk) do not burn the GPU, so one pod can keep roughly **20–40 live sessions** connected. Size the fleet from **peak concurrent sessions**, not from DAU alone — e.g. 5,000 DAU at a 2% peak ⇒ ~100 concurrent ⇒ you need several GPUs, not one.

Scaling rule of thumb — why these numbers

We size GPUs from **peak concurrent connected sessions**, assuming:

- ~1 GPU handles ~20–40 comfortable connected sessions (VAD), with 1–3 GPU-busy turns
- Above that, add GPUs **linearly** and put a queue / load balancer in front
- Beyond ~100 concurrent, prefer **RunPod Serverless workers** or many pods so cold capacity can appear only at peak

Peak concurrent voice sessions	GPUs needed (24 GB)	Why
≤ 25	1	Fits one 4090 connected budget with margin
26–50	2	Split traffic; failover if one pod dies
51–120	4–6	Growth-stage peaks; keep p95 latency stable
121–250	8–12	Scale-stage; still pod-based is fine
250+	Serverless / large pod fleet	Spiky load; paying 24/7 for max peak wastes money

3.3 Bandwidth estimates (realistic)

Per turn (Opus 32 kbps $\approx$ 4 KB/s each way):

- User speech $\sim$ 60 s $\rightarrow$ **$\sim$ 240 KB** in
- Robot speech $\sim$ 35 s $\rightarrow$ **$\sim$ 140 KB** out
- +25% overhead $\rightarrow$ **$\sim$ 475 KB / turn** ($\sim$ 0.46 MB)

Stage	Turns/day	Data/day	Data/month	Notes
Pilot (100 DAU)	600	$\sim$ 0.28 GB	$\sim$8 GB	Still small
Soft (1,000)	8,000	$\sim$ 3.7 GB	$\sim$110 GB	Usually inside generous VPS allowances
Growth (5,000)	50,000	$\sim$ 23 GB	$\sim$700 GB	Watch egress fees on hyperscalers
Scale (25,000)	300,000	$\sim$ 140 GB	$\sim$4.2 TB	Need cheap egress (Hetzner-like) or CDN; don't archive WAV on the GPU box
Mature (100,000)	1,200,000	$\sim$ 560 GB	$\sim$17 TB	Object storage + egress contracts required
+ raw WAV archive (16-bit/16 kHz mono)	—	—	$\times$10–20 vs Opus	Keep compressed Opus for transport; archive selectively

Always-open mic worst case (no VAD): $\sim$ 8 KB/s bidirectional $\approx$ **$\sim$ 0.7 GB/hour/session**. Twenty always-on sessions $\approx$ **$\sim$ 10 TB/month** — avoid this design; use **VAD or push-to-talk**.

Egress watchlist: AWS / some DigitalOcean paths bill egress heavily; Hetzner / Contabo often include multi-TB; RunPod / Vast.ai compute is separate from **public egress and volume storage** — confirm in the console before Scale.

3.4 Storage

Item	Size guidance
Model weights (Turbo + Nile + VoiceTut)	$\sim$15–25 GB on disk
Docker / CUDA / deps	$\sim$20–40 GB
Working / logs (7 days)	$\sim$20–100 GB at Growth
Recommended disk	150–300 GB NVMe on the GPU pod + object storage for archives

4. VPS / GPU provider comparison (July 2026)

Prices move weekly. Figures below are **public on-demand listings** from provider pages and 2026 comparison aggregators. **Re-check before purchase.**

4.1 Scorecard (fit for *this* Arabic voice stack)

Provider	Interact (SSH/API)	RTX 4090- class \$/hr	Reliability	Always-on monthly*	Best use	Score /10
RunPod Secure	Excellent	~0.69	High (DC)	~\$497	Production default	9.0
RunPod Community	Excellent	~0.34	Medium	~\$245	Dev / staging	8.2
Vast.ai	Good	~0.27–0.37	Variable (P2P)	~\$195–270	Cheap experiments	6.5
Hetzner	Excellent	~0.33 (RTX 4000 Ada 20GB)	High EU	~\$240	Always-on EU, predictable	7.8
DigitalOcean	Excellent	RTX 4000 ~0.76; H100 3.39	High	RTX4k ~\$547	Simple DX / team	7.0
Vultr	Excellent	A100 from ~1.29; H100 ~2.30	High	A100 ~\$930	Enterprise-ish	6.8
Lambda Labs	Good	No 4090; A100/H100 focus	High + SLA	A100 ~\$940+	Training / big models	6.0
Contabo	Good	4090 ~0.89 listed; monthly AI boxes	Medium	4090 ~\$640+ / Ada4000 ~€549	Budget monthly EU	6.2
AWS / GCP / Azure	Excellent	2–3× specialist rates	Highest	Very high	Compliance only	4.5

*24/7 ≈ ×720 hours. Spot / reserved can cut 20–50%.

4.2 Why RunPod over Vast.ai if the GPU is “the same”?

Yes — both can rent an **RTX 4090 24 GB**. You still pick **RunPod Secure** for production because you are buying **operations quality**, not only FLOPS:

Factor	RunPod Secure	Vast.ai marketplace
Who owns/runs the box	Datacenter partners under RunPod’s Secure program	Random hosts bidding prices
Uptime / eviction	Production-oriented; formal SLA story	Host can be slow, full, or interruptible; reliability scores vary

Factor	RunPod Secure	Vast.ai marketplace
API / DX	Strong pod + Serverless product, templates, docs	Good CLI/API, but more “DIY marketplace”
Client voice data	Better compliance / isolation narrative	Harder to defend in a client security review
Debugging a live outage	One vendor support path	“Which host failed?” becomes your problem
Price	Higher	Often cheapest 4090

Use Vast.ai when: training experiments, load tests, non-customer traffic, or you accept interrupt risk to save ~30–50%.

Use RunPod Secure when: real users speak Arabic into your robot and downtime = lost trust.

Community RunPod sits **between** them: cheaper than Secure, more curated than raw Vast.ai, still weaker than Secure for go-live.

4.3 Serverless / pay-for-what-you-use — 3 hours/day vs full day

Important: “Serverless” and “Pods” bill differently.

Product style	Providers	If you only need 3 GPU hours / day	If you leave it on 24/7
Serverless / scale-to-zero	RunPod Serverless, Vast.ai Serverless	You pay roughly 3 hours × \$/hr of worker time (plus short idle timeout after last request, often seconds–minutes; plus storage) — not a full day	Only if traffic is continuous or you keep “active workers” warm
On-demand Pod / instance you start & stop	RunPod Pods, Vast.ai instances	3 hours × \$/hr if you stop/destroy after use	Full 24 × \$/hr if you forget to stop
VM that still bills when powered off	DigitalOcean GPU Droplets (official caveat)	Power-off may still bill reserved GPU — you must destroy to stop compute	Full month either way if the droplet exists
Monthly dedicated	Contabo / some Hetzner dedicated	You usually pay the full month even if you use 3 hours/day	Same monthly price

Example — RTX 4090 ~\$0.69/hr Secure Pod

Usage pattern	Approx. monthly compute
3 hours/day × 30 days = 90 h	90 × 0.69 ≈ \$62 (if stopped when idle)
Business day 10 h × 22 days = 220 h	≈ \$152
Always on 720 h	≈ \$497

Same math on Community (~\$0.34/hr) or Vast.ai (~\$0.30/hr): **3 hours/day $\approx 90 \times$ rate, not the 24/7 price — only if** the product is truly metered and you (or Serverless) scale to zero.

Serverless caveat for voice: cold start (container + load ~14 GB of models) can add **seconds to tens of seconds** unless you keep a warm worker. For a live robot, many teams keep **1 warm Secure pod** during business hours and use Serverless only for overflow.

4.4 Detailed provider notes

RunPod (recommended)

- **Products:** Pods (persistent), Serverless (autoscaling endpoints), Instant Clusters.
- **Tiers:** Community (cheaper hosts) vs Secure (vetted datacenters) — see §1 detailed table.
- **Why it fits:** Deploy Docker with CUDA, expose HTTP for ASR/LLM/TTS APIs, scale pods when concurrency rises, stop billing when terminated (per-second).
- **Suggested SKUs:**
 - Dev: **1 × RTX 4090 Community** (~\$0.34/hr)
 - Prod: **1 × RTX 4090 Secure** (~\$0.69/hr) → add pods as concurrency grows
 - Optional later: Serverless workers for burst traffic
- **Watch:** Network volume storage is billed even when compute is stopped; keep models on a volume, destroy unused pods.

Vast.ai

- Marketplace / bidding; often cheapest 4090 (~\$0.27–0.37/hr median).
- Also has **Serverless** (per-second, autoscaling) similar in *billing shape* to RunPod Serverless.
- **Pros:** Cost. **Cons:** Host variability, interrupt risk, weaker production SLA / client compliance story.
- Use for bake-offs and load tests, not sole production path for a client-facing robot.

Hetzner

- Strong EU footprint, generous traffic pools on many plans, good SSH/root UX.
- RTX 4000 Ada ~20 GB (~\$0.33/hr listed) — **borderline** for quality stack; prefer RTX 6000 Ada / larger if available.
- Best when you want **stable monthly** EU hosting and lower surprise egress bills (often closer to “full month” economics).

DigitalOcean

- Excellent docs, VPC, managed DB, simple GPU Droplets.
- RTX 4000 Ada **\$0.76/hr**; L40S **\$1.57/hr**; H100 **\$3.39/hr** (official docs, 2026).
- **Caveat:** powered-off GPU Droplets **still bill** — destroy to stop charges (not true scale-to-zero serverless for this stack).
- Good if the team already lives in DO; otherwise RunPod is cheaper for 4090-class inference.

Vultr / Lambda / Contabo

- **Vultr:** solid Cloud GPU (A100/H100); overkill \$ for this ≤ 24 GB stack.

- **Lambda**: great for training clusters / SLA; weak consumer-GPU catalog.
- **Contabo**: monthly AI dedicated (e.g. Ada 4000 ~€549/mo listed) can beat 24/7 RunPod Secure if utilization is always-on — but **3 hours/day still costs the full month**.

4.5 Cost scenarios for *our* stack

Assumptions: **1 × RTX 4090**, public API.

Scenario	Hours GPU / mo	RunPod Community	RunPod Secure	Vast.ai (~\$0.30)	Notes
3 h/day metered (Serverless or start/stop)	90	~\$31	~\$62	~\$27	True pay-per-use
Nightly tests only	60	~\$20	~\$41	~\$18	CI / bake-offs
Business hours API (10×22)	220	~\$75	~\$152	~\$66	Stop pod nights
Soft launch 24/7	720	~\$245	~\$497	~\$216	1 GPU warm always
Growth (2 GPUs 24/7)	1,440	~\$490	~\$994	~\$432	~5k DAU class peaks
Scale (6 GPUs 24/7)	4,320	~\$1,470	~\$2,980	~\$1,300	~25k DAU class

Add ~\$10–40/mo object storage + ~\$5–20/mo small CPU edge (TLS / gateway) if split.

Break-even insight: If real usage is only a few hours/day, **RunPod/Vast metered or Serverless** wins. If the robot must answer with **low latency 24/7**, compare Secure 24/7 vs Contabo/Hetzner monthly quotes.

5. Recommended deployment architecture

▼
Object storage (WAV logs, analytics) – optional region near EG/EU

Interaction checklist (why RunPod works for the team)

1. Create Secure pod with CUDA + PyTorch template
2. `scp` / volume-mount weights; expose FastAPI/gRPC ports
3. Automate via RunPod API (create/stop pods from CI)
4. Add second pod when p95 turn latency > target (e.g. 3 s)
5. Move burst traffic to Serverless workers if traffic is spiky

6. Final selection matrix

Decision	Choice
Default ASR	Whisper-Large-v3-Turbo-CT2
Default LLM	Nile-Chat-4B (speed UX)
Quality LLM alt	Qwen3-8B int4
Default TTS	VoiceTut-TTS (listen to confirm)
GPU class	24 GB (RTX 4090 or better)
Provider	RunPod Secure Cloud
Dev / cost lane	RunPod Community or Vast.ai
Always-on EU alt	Hetzner / Contabo monthly quote
Pilot capacity	1 GPU → ~100–500 DAU
Soft launch	1–2 GPUs → ~1,000–2,500 DAU
Growth	2–6 GPUs → ~5,000 DAU class
Scale	Autoscaling pods / Serverless; plan multi-TB egress if WAV archived
